

EXHIBIT 010

U.S. Patent No. 7,769,893 (Goossens)**“Integrated circuit and method for establishing transactions”**

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
<p>4. A method for exchanging messages in an integrated circuit comprising a plurality of modules, the messages between the plurality of modules being exchanged via a network</p>	<p>Without conceding that the preamble of claim 4 of the '9893 Patent is limiting, Qualcomm Incorporated and Qualcomm Technologies, Inc.'s (hereinafter, “Qualcomm”) Snapdragon 8+ Gen 1 Mobile Platform (together, the “Snapdragon SoC”) is an integrated circuit and performs a method for exchanging messages in an integrated circuit comprising a plurality of modules, the messages between the plurality of modules being exchanged via a network, either literally or under the doctrine of equivalents.</p> <div data-bbox="510 534 636 656">  </div> <h2 data-bbox="661 570 1606 626">Snapdragon 8+ Gen 1 Mobile Platform</h2> <p data-bbox="510 846 1728 911">New power and performance enhancements deliver the ultimate boost across all your on-device experiences.</p> <p data-bbox="510 976 1707 1162">The Snapdragon® 8+ Gen 1 Mobile Platform is our premium-tier powerhouse. Qualcomm® Adreno™ GPU offers a 10% increase in GPU clock speeds and 30% GPU power reduction while the Qualcomm® Kryo™ CPU provides 10% better CPU performance and 30% CPU improved power efficiency. Plus, this platform delivers additional power savings and extended performance across the board—including over 80 minutes longer video streaming and more than 50 minutes longer web browsing.</p>

¹ The Snapdragon SoC is charted as a representative product made used, sold, offered for sale, and/or imported by or on behalf of Qualcomm. The citations to evidence contained herein are illustrative and should not be understood to be limiting. The right is expressly reserved to rely upon additional or different evidence, or to rely on additional citations to the evidence cited already cited herein.

U.S. Patent No. 7,769,893 (Goossens)

“Integrated circuit and method for establishing transactions”

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
	<p>The Arteris NoC exchanges messages between the plurality of modules via a network in the Snapdragon SoC.</p> <p>For example, in the Arteris NoC, “[m]ost transactions require the following two-step transfers,” including “[a] master send[ing] request packets” and “the slave return[ing] response packets”:</p> <p>11.3.1.1 Transaction Layer</p> <p>The transaction layer is compatible with bus-based transaction protocols used for on-chip communications. It is implemented in NIUs, which are at the boundary of the NoC, and translates between third-party and NTTP protocols. Most transactions require the following two-step transfers:</p> <ul style="list-style-type: none"> • A master sends request packets. • Then, the slave returns response packets. <p>As shown in Figure 11.1, requests from an initiator are sent through the master NIU’s transmit port, Tx, to the NoC request network, where they are routed to the corresponding slave NIU. Slave NIUs, upon reception of request packets</p>

U.S. Patent No. 7,769,893 (Goossens)*“Integrated circuit and method for establishing transactions”*

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
	<p>on their receive ports, Rx, translate requests so that they comply with the protocol used by the target third-party IP node. When the target node responds, returning responses are again converted by the slave NIU into appropriate response packets, then delivered through the slave NIU's Tx port to the response network. The network then routes the response packets to the requesting master NIU, which forwards them to the initiator. At the transaction level, NIUs enable multiple protocols to coexist within the same NoC. From the point of view of the NTTP modules, different third-party protocols are just packets moving back and forth across the network.</p>

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
	<p style="text-align: center; color: orange; font-weight: bold;">Connectivity Map → Interconnect Connections → Layout</p> <div style="display: flex; justify-content: space-around; align-items: flex-start;">  <div style="text-align: center;">  <p>DC-Topographical</p> </div>  </div> <ul style="list-style-type: none"> • Connectivity table defines interconnect connections within the floorplan • Routes must pass through available channels in the floorplan • Connectivity passes from initiator NIU to switch, to link, to RC buffers and finally to target NIU <div style="display: flex; justify-content: space-between; font-size: small; margin-top: 20px;"> <div data-bbox="508 966 644 993">ARTERISIP</div> <div data-bbox="1106 971 1264 989">ISPD 2018, 28 March 2018</div> <div data-bbox="1652 971 1877 989">Copyright © 2018 Arteris IP 12</div> </div> <p>See Physical Interconnect Aware Network Optimizer, http://www.ispd.cc/slides/2018/s7_2.pdf, at slide 12.</p> <p>As a further illustration, the “Arteris NTTP protocol is packet-based” and the packets, which have “header and necker cells [that] contain information relative to routing, payload size, packet type, and the packet target address,” are “transported to other parts of the NoC to accomplish the transactions that are required by foreign IP nodes”:</p>

U.S. Patent No. 7,769,893 (Goossens)

“Integrated circuit and method for establishing transactions”

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
	<p>11.3.1.2 Transport Layer</p> <p>The Arteris NTTP protocol is packet-based. Packets created by NIUs are transported to other parts of the NoC to accomplish the transactions that are required by foreign IP nodes. All packets are comprised of cells: a header cell, an optional necker cell, and possibly one or more data cells (for packet definition see Figure 11.2; further descriptions of the packet can be found in the next subsection). The header and necker cells contain information relative to routing, payload size, packet type, and the packet target address. Formats for request packets and response packets are slightly different, with the key difference being the presence of an additional cell, the necker, in the request packet to provide detailed addressing information to the target.</p> <p>See Networks-On-Chips Theory and Practice, https://vdoc.pub/download/networks-on-chips-theory-and-practice-embedded-multi-core-systems-6f26qivv11f0, at 313.</p> <p>As a further example, the packets sent in the Arteris NoC are “composed of cells that are organized into fields, with each field carrying specific information,” including “Slave address” and “Slave offset”:</p>

U.S. Patent No. 7,769,893 (Goossens)

“Integrated circuit and method for establishing transactions”

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
	<p>FIGURE 11.2 NTTP packet structure.</p> <p>Networks-On-Chips Theory and Practice, https://vdoc.pub/download/networks-on-chips-theory-and-practice-embedded-multi-core-systems-6f26qivv11f0, at 313, 314-315.</p> <p>As a further example, “[i]nitiator NIU units...translate[] AHB transactions AHB transactions into an equivalent NTTP packet sequence, and transports requests and responses to and from a target NIU, that is, slave IP” and the “AHB-to-NTTP unit instantiates a Translation Table for address decoding” with the table “receiv[ing] 32-bit AHB addresses from the NIU and returns the packet header and necker information that is needed to access the NTTP address space: Slave address, Slave offset, Start offset, and the coherency size”:</p>

U.S. Patent No. 7,769,893 (Goossens)

“Integrated circuit and method for establishing transactions”

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
	<p data-bbox="520 264 1031 302">11.3.2.1 Initiator NIU Units</p> <p data-bbox="520 323 1835 971">Initiator NIU units (the architecture of the AHB initiator is given in Figure 11.4) enable connection between an AMBA-AHB master IP and the NoC. It translates AHB transactions into an equivalent NTTP packet sequence, and transports requests and responses to and from a target NIU, that is, slave IP (slave can be any of the supported protocols). The AHB-to-NTTP unit instantiates a Translation Table for address decoding. This table receives 32-bit AHB addresses from the NIU and returns the packet header and necker information that is needed to access the NTTP address space: Slave address, Slave offset, Start offset, and the coherency size (see Figure 11.2). Whenever the AHB address does not fit the predefined decoding range, the table asserts an error signal that sets the error bit of the corresponding NTTP request packet, for further error handling by the NoC. The translation table is fully user-defined at design time: it must first be completed with its own hardware parameters, then passed to the NIU.</p> <p data-bbox="520 1027 1803 1101">Networks-On-Chips Theory and Practice, https://vdoc.pub/download/networks-on-chips-theory-and-practice-embedded-multi-core-systems-6f26qivv11f0, at 317.</p> <p data-bbox="520 1146 1877 1260">As further example, “[f]or the AHB target NIU, the AHB address space is mapped from the NTTP address space using the slave offset, the start/stop offset, and the slave address fields, when applicable (from the header of the request packet, Figure 11.2)”:</p>

U.S. Patent No. 7,769,893 (Goossens)

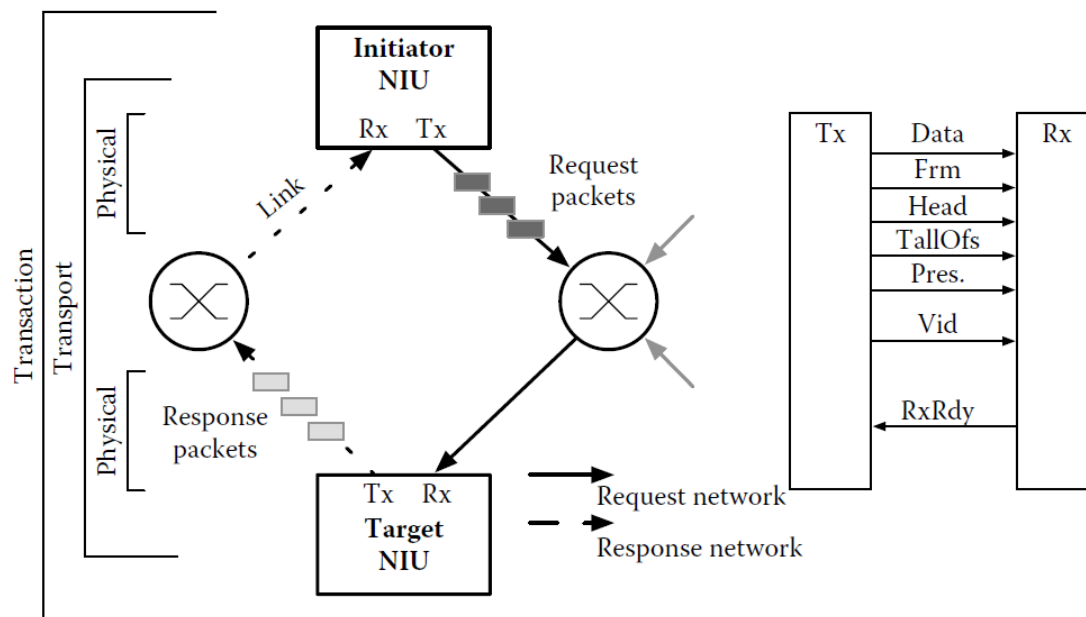

“Integrated circuit and method for establishing transactions”

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
	<p>11.3.2.2 Target NIU Units</p> <p>Target NIU units enable connection of a slave IP to the NoC by translating NTTP packet sequences into equivalent packet transactions, and transporting requests and responses to and from targets (the architecture of the AHB Target NIU is given in Figure 11.5). For the AHB target NIU, the AHB address space is mapped from the NTTP address space using the slave offset, the start/stop offset, and the slave address fields, when applicable (from the header of the request packet, Figure 11.2). The AHB address bus is always</p> <p><i>Id.</i> at 318.</p>
<p>the method including the steps of:</p> <p>(a) issuing from said addressing module M a message request including said first information, said second information, and data and/or connection properties to an address</p>	<p>The Arteris NoC utilized by the Snapdragon SoC issues from said addressing module M a message request including said first information, said second information, and data and/or connection properties to an address translation unit included as part of an active network interface module associated with said addressing module M, either literally or under the doctrine of equivalents.</p> <p>For example, the Arteris NoC used in the Snapdragon SoC uses Network Interface Units (NIUs), which “translate[] between third-party [OCP, AMBA AHB, APB, and AXI protocols] and NTTP protocols” and in the Arteris NoC, “[m]ost transactions require the following two-step transfers,” including “[a] master send[ing] request packets” and “the slave return[ing] response packets”:</p>

U.S. Patent No. 7,769,893 (Goossens)

“Integrated circuit and method for establishing transactions”

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
translation unit included as part of an active network interface module associated with said addressing module M,	<p data-bbox="558 266 1020 305">11.3.1.1 Transaction Layer</p> <p data-bbox="558 323 1822 500">The transaction layer is compatible with bus-based transaction protocols used for on-chip communications. It is implemented in NIUs, which are at the boundary of the NoC, and translates between third-party and NTTP protocols. Most transactions require the following two-step transfers:</p> <ul data-bbox="632 545 1350 641" style="list-style-type: none"> • A master sends request packets. • Then, the slave returns response packets. <p data-bbox="558 686 1822 816">As shown in Figure 11.1, requests from an initiator are sent through the master NIU's transmit port, Tx, to the NoC request network, where they are routed to the corresponding slave NIU. Slave NIUs, upon reception of request packets</p> <p data-bbox="548 846 1843 1255">on their receive ports, Rx, translate requests so that they comply with the protocol used by the target third-party IP node. When the target node responds, returning responses are again converted by the slave NIU into appropriate response packets, then delivered through the slave NIU's Tx port to the response network. The network then routes the response packets to the requesting master NIU, which forwards them to the initiator. At the transaction level, NIUs enable multiple protocols to coexist within the same NoC. From the point of view of the NTTP modules, different third-party protocols are just packets moving back and forth across the network.</p>

See Physical Interconnect Aware Network Optimizer, http://www.ispd.cc/slides/2018/s7_2.pdf, at slide 12.

As a further illustration, the “Arteris NTTP protocol is packet-based” and the packets, which have “header and necker cells [that] contain information relative to routing, payload size, packet type, and the packet target address,” are “transported to other parts of the NoC to accomplish the transactions that are required by foreign IP nodes”:

U.S. Patent No. 7,769,893 (Goossens)

“Integrated circuit and method for establishing transactions”

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
	<p data-bbox="512 266 921 305">11.3.1.2 Transport Layer</p> <p data-bbox="512 321 1709 743">The Arteris NTTP protocol is packet-based. Packets created by NIUs are transported to other parts of the NoC to accomplish the transactions that are required by foreign IP nodes. All packets are comprised of cells: a header cell, an optional necker cell, and possibly one or more data cells (for packet definition see Figure 11.2; further descriptions of the packet can be found in the next subsection). The header and necker cells contain information relative to routing, payload size, packet type, and the packet target address. Formats for request packets and response packets are slightly different, with the key difference being the presence of an additional cell, the necker, in the request packet to provide detailed addressing information to the target.</p> <p data-bbox="512 764 632 797"><i>Id.</i> at 313.</p> <p data-bbox="512 846 1806 997">As yet a further illustration, packets in the Arteris NoC are “delivered as words that are sent along links and “[o]ne link (represented in Figure 11.1) defines the following signals,” which include “the current priority of the packet used to define preferred traffic class (or Quality of Service)” and “[f]low control”:</p>

U.S. Patent No. 7,769,893 (Goossens)

“Integrated circuit and method for establishing transactions”

maximum cell-width (header, necker, and data cell) and the link-width. One link (represented in [Figure 11.1](#)) defines the following signals:

- **Data**—Data word of the width specified at design-time.
- **Frm**—When asserted high, indicates that a packet is being transmitted.
- **Head**—When asserted high, indicates the current word contains a packet header. When the link-width is smaller than single (SGL), the header transmission is split into several word transfers. However, the Head signal is asserted during the first transfer only.
- **TailOfs**—Packet tail: when asserted high, indicates that the current word contains the last packet cell. When the link-width is smaller than single (SGL), the last cell transmission is split into several word transfers. However, the Tail signal is asserted during the first transfer only.
- **Pres.**—Indicates the current priority of the packet used to define preferred traffic class (or Quality of Service). The width is fixed during the design time, allowing multiple pressure levels within the same NoC instance (bits 3–5 in [Figure 11.2](#)).
- **Vld**—Data valid: when asserted high, indicates that a word is being transmitted.
- **RxRdy**—Flow control: when asserted high, the receiver is ready to accept word. When de-asserted, the receiver is busy.

This signal set, which constitutes the Media Independent NoC Interface (MINI), is the foundation for NTTP communications.

The AHB address bus is always</p> <p><i>Id.</i> at 318.</p> <p>As a further illustration, the Arteris NoC implements Quality of Service (QoS) to “provide[] a regulation mechanism allowing specification of guarantees on some of the parameters related to the traffic”; “QoS, which includes guarantees of throughput and/or latency, is achieved by exploiting the signal pressure embedded into the NTTP packet definition” where the “pressure signal can be generated by the IP itself and is typically linked to a certain level of urgency with which the transaction will have to be completed”; and the “pressure information will be embedded in the NTTP packet at the NIU level”:</p>

U.S. Patent No. 7,769,893 (Goossens)

“Integrated circuit and method for establishing transactions”

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
	<p>Quality of Service (QoS). The QoS is a very important feature in the inter-connect infrastructures because it provides a regulation mechanism allowing specification of guarantees on some of the parameters related to the traffic. Usually the end users are looking for guarantees on bandwidth and/or end-to-end communication latency. Different mechanisms and strategies have been proposed in the literature. For instance, in <i>Æthereal NoC</i> [11,24] proposed by NXP, a TDMA approach allows the specification of two traffic categories [25]: BE and GT.</p> <p>In the <i>Arteris NoC</i>, the QoS is achieved by exploiting the signal pressure embedded into the NTTP packet definition (Figures 11.1 and 11.2). The pressure</p>

U.S. Patent No. 7,769,893 (Goossens)*“Integrated circuit and method for establishing transactions”*

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
	<p>signal can be generated by the IP itself and is typically linked to a certain level of urgency with which the transaction will have to be completed. For example, we can imagine associating the generation of the pressure signal when a certain threshold has been reached in the FIFO of the corresponding IP. This pressure information will be embedded in the NTTP packet at the NIU level: packets that have pressure bits equal to zero will be considered without QoS; packets with a nonzero value of the pressure bit will indicate preferred traffic class.* Such a QoS mechanism offers immediate service to the most urgent inputs and variables, and fair service whenever there are multiple contending inputs of equal urgency (BE). Within switches, arbitration decisions favor preferred packets and allocate remaining bandwidth (after preferred packets are served) fairly to contending packets. When there are contending preferred packets at the same pressure level, arbitration decisions among them are also fair.</p> <p>The Arteris NoC supports the following four different traffic classes:</p>

U.S. Patent No. 7,769,893 (Goossens)

“Integrated circuit and method for establishing transactions”

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
	<ul style="list-style-type: none"> • Real time and low latency (RTLL)—Traffic flows that require the lowest possible latency. Sometimes it is acceptable to have brief intervals of longer latency as long as the average latency is low. Care must be taken to avoid starving other traffic flows as a side effect of pursuing low latency. • Guaranteed throughput (GT)—Traffic flows that must maintain their throughput over a relatively long time interval. The actual bandwidth needed can be highly variable even over long intervals. Dynamic pressure is employed for this traffic class. • Guaranteed bandwidth (GBW)—Traffic flows that require a guaranteed amount of bandwidth over a relatively long time interval. Over short periods, the network may lag or lead in providing this bandwidth. Bandwidth meters may be inserted onto links in the NoC to regulate these flows, using either of the two methods. If the flow is assigned high pressure, the meter asserts backpressure (flow control) to prevent the flow from exceeding a maximum bandwidth. Alternatively, the meter can modulate the flows pressure (priority) dynamically as needed to maintain an average bandwidth. • Best effort (BE)—Traffic flows that do not require guaranteed latency or throughput but have an expectation of fairness.

'9893 Patent Claim	Qualcomm Snapdragon 8+ Gen 1 Mobile Platform System on Chip ¹
	<p>11.3.2.1 Initiator NIU Units</p> <p>Initiator NIU units (the architecture of the AHB initiator is given in Figure 11.4) enable connection between an AMBA-AHB master IP and the NoC. It translates AHB transactions into an equivalent NTTP packet sequence, and transports requests and responses to and from a target NIU, that is, slave IP (slave can be any of the supported protocols). The AHB-to-NTTP unit instantiates a Translation Table for address decoding. This table receives 32-bit AHB addresses from the NIU and returns the packet header and necker information that is needed to access the NTTP address space: Slave address, Slave offset, Start offset, and the coherency size (see Figure 11.2). Whenever the AHB address does not fit the predefined decoding range, the table asserts an error signal that sets the error bit of the corresponding NTTP request packet, for further error handling by the NoC. The translation table is fully user-defined at design time: it must first be completed with its own hardware parameters, then passed to the NIU.</p> <p>Networks-On-Chips Theory and Practice, https://vdoc.pub/download/networks-on-chips-theory-and-practice-embedded-multi-core-systems-6f26qivv11f0, at 317.</p>
(c) determining, at said address translation unit, which message receiving module S is being addressed in said	<p>The Arteris NoC utilized by the Snapdragon SoC determines, at said address translation unit, which message receiving module S is being addressed in said message request issued from said addressing module M based on said single address, either literally or under the doctrine of equivalents.</p> <p>For example, the Arteris NoC used by the Snapdragon SoC uses Network Interface Units (NIUs), which “translate[] between third-party [OCP, AMBA AHB, APB, and AXI protocols] and NTTP</p>

message request issued from said addressing module M based on said single address, and	<p>protocols” and in the Arteris NoC, “[m]ost transactions require the following two-step transfers,” including “[a] master send[ing] request packets” and “the slave return[ing] response packets”:</p> <p>11.3.1.1 Transaction Layer</p> <p>The transaction layer is compatible with bus-based transaction protocols used for on-chip communications. It is implemented in NIUs, which are at the boundary of the NoC, and translates between third-party and NTTP protocols. Most transactions require the following two-step transfers:</p> <ul style="list-style-type: none"> • A master sends request packets. • Then, the slave returns response packets. <p>As shown in Figure 11.1, requests from an initiator are sent through the master NIU’s transmit port, Tx, to the NoC request network, where they are routed to the corresponding slave NIU. Slave NIUs, upon reception of request packets on their receive ports, Rx, translate requests so that they comply with the protocol used by the target third-party IP node. When the target node responds, returning responses are again converted by the slave NIU into appropriate response packets, then delivered through the slave NIU’s Tx port to the response network. The network then routes the response packets to the requesting master NIU, which forwards them to the initiator. At the transaction level, NIUs enable multiple protocols to coexist within the same NoC. From the point of view of the NTTP modules, different third-party protocols are just packets moving back and forth across the network.</p>
